JOB MARKET PAPER

On-the-Job Search over the Business Cycle: Evidence from the United Kingdom

Little is known about the cyclical properties of on-the-job search (OJS) effort of employed workers. This paper provides new evidence that aggregate OJS effort rises during a recession, as more workers start searching on-the-job and average search intensity increases when unemployment is higher. To explore this further, this paper leverages the panel structure of the UK Labour Force Survey to account for compositional changes in the pool of employed workers and job seekers over the business cycle. In particular, this paper finds that higher unemployment increases the probability that a worker engages in OJS due to fear of job loss and the probability that a worker engages in OJS for an additional job. It also finds that higher unemployment increases the number of methods that job seekers use to search for another job. Results have important macroeconomic implications, as they suggest that employed workers are crowding out the job search of unemployed workers during a recession.
